In genetics, dominance pertains to a gene or allele expressed over the other genes or alleles. There are three major forms: complete dominance , incomplete dominance , and codominance . When an individual inherited two dominant alleles (e.g. AA ) or inherits at least one dominant allele (e.g. Aa ), that individual will show the trait because of the presence of the dominant allele.

Codominance is a relationship between two versions of a gene. Individuals receive one version of a gene, called an allele, from each parent. If the alleles are different, the dominant allele usually will be expressed, while the effect of the other allele, called recessive, is masked. In codominance, however, neither allele is recessive and the phenotypes of both alleles are expressed.

Multiple alleles, incomplete dominance, and codominance In the real world, genes often come in many versions (alleles). Alleles aren't always fully dominant or recessive to one another, but may instead display codominance or incomplete dominance.

Codominance, in genetics, phenomenon in which two alleles (different versions of the same gene) are expressed to an equal degree within an organism. As a result, traits associated with each allele are displayed simultaneously. An example of codominance is seen in the MN blood group system of humans. MN blood type is governed by two alleles, M and N. Individuals who are homozygous for the M allele have a surface molecule (called the M antigen) on their red blood cells.
